## Design of Dynamic Work

Estimation of Metabolic Rate

- ISO Components Method
- MVMA Method of Bernard and Joseph
- Manual Materials Handling
- External Work Method

Estimation of Maximum Aerobic Capacity

- Distributions of Maximum Aerobic Capacities
- Table of Design Goals

Estimation of Endurance Time
Estimation of Recovery Time

## Estimation of Metabolic Rate

Adapted from ISO Components Method

| Components | Initial Data | Values | Rate of Energy Expenditure [W] |
| :---: | :---: | :---: | :---: |
| Base | --- | --- | 80 |
| Posture | Sit | 20 |  |
|  | Stand | 45 |  |
| Activity | Body Involvement <br> N H 1A 2A WB | See Activity Matrix |  |
|  | $$ |  |  |
| Horizontal Rate of Travel - Average in Feet / Min | Estimate [ft/min]: <br> $2.5 \mathrm{mph}=220 \mathrm{ft} / \mathrm{min}$ | 1.0 x Rate [ft/min] |  |
| Vertical Rate of Travel - Average in Feet / Min | Estimate [ft/min]: <br> $1 \mathrm{step} / 2 \mathrm{sec}=15 \mathrm{ft} / \mathrm{min}$ (ie, 6-inch step) | 17 x Rate [ft/min] |  |
|  |  | otal Metabolic Rate um the Last Column) |  |

|  | Effort |  |  |  |
| ---: | :---: | :---: | :---: | :---: |
| Activity | Light | Moderate | Heavy | Very Heavy |
| None | 0 | 0 | 0 | 0 |
| Hand(s) Only | 25 | 55 | 70 | 80 |
| One Arm | 65 | 100 | 135 | 170 |
| Both Arms | 115 | 155 | 190 | 230 |
| Whole Body | 225 | 340 | 505 | 700 |
|  | Can be <br> performed <br> indefinitely with <br> ease | Can be <br> performed <br> indefinitely with <br> some effort | Can be <br> performed for 30 <br> -60 min before a <br> break | Can be <br> performed for <br> about 15 min <br> before a break |

## Estimation of Metabolic Rate

Adapted from the MVMA Qualitative Method of Bernard and Joseph

| Components | Initial Data | Values | Rate of <br> Energy Expenditure [W] |
| :---: | :---: | :---: | :---: |
| Base | --- | --- | 100 |
| Arms | AI (for use with Lift) <br> 0 : Sedentary <br> 0: Little Hand/Arm Movement <br> 1: Hands Move Mostly $<20$ in <br> 2: Frequently Hands Move $>20$ in <br> 3: Bend, stoop, extended reaches | $\begin{gathered} 0 \\ 69 \\ 98 \\ 127 \\ 156 \end{gathered}$ |  |
| Lift <br> (not appropriate for heavy manual materials handling) | Weight of Parts and Tools [lb] <br> Wt: <4 4 to $11>11$ <br> WI: $1 \begin{array}{llll} & 2 & 3\end{array}$ <br> Frequency [cycles / min] <br> Frq: $<2$ to $5>5$ <br> FI: 1023 | AI x <br> WI x <br> FI x <br> 5.1 |  |
| Walk Average in Feet / Min (Do not include push / pull) | Estimated Rate [ft/min]: <br> $2.5 \mathrm{mph}=220 \mathrm{ft} / \mathrm{min}$ | 1.0 x Rate [ft/min] |  |
| Push / Pull | Average Force [lb] = $\qquad$ $\{\mathrm{F}\}$ <br> Average Distance per Minute $[\mathrm{ft} / \mathrm{min}]=$ $\qquad$ \{D $\}$ | $\begin{gathered} (6+1.3 \times F) \\ x \mathrm{D} / 3 \end{gathered}$ |  |
| Vertical Rate of Travel Average in Feet / Min | Estimated Rate [ft/min]: <br> $1 \mathrm{step} / 2 \mathrm{sec}=15 \mathrm{ft} / \mathrm{min}$ (ie, 6 -inch step) | 17 x Rate [ft/min] |  |
| Total Metabolic Rate (Sum the Last Column) |  |  |  |

## Estimation of Metabolic Rate for Materials Handling Tasks

Adapted from Garg and NIOSH
$\mathrm{L}=$ average load in pounds
Freq $=$ average lifting rate in lifts per minute
$\mathrm{M}=$ metabolic rate in watts [W]

Lifting that requires a stoop (e.g., below the waist)
$\mathrm{M}[\mathrm{W}]=117+(12.9+0.46 \mathrm{~L}[\mathrm{lb}]) \times$ Freq [lifts/min $]$

Lifting that predominately involves arms (e.g., above the waist)
$\mathrm{M}[\mathrm{W}]=117+(2.14+0.66 \mathrm{~L}[\mathrm{lb}]) \times$ Freq [lifts/min $]$

## Estimation of Metabolic Rate for External Work by Arms or Legs Adapted from Kamon

Not applicable to pushing or pulling while walking
$\mathrm{W}_{\mathrm{ex}}=$ external work rate estimated as the force in pounds times the average rate of distance moved or applied $=\mathrm{F}_{\mathrm{ex}} \times \mathrm{D}_{\mathrm{ex}}[\mathrm{ft} \mathrm{lb} / \mathrm{min}]$
$\mathrm{F}_{\mathrm{ex}}=$ average force applied or exerted in pounds [lb]
$\mathrm{D}_{\text {ex }}=$ average distance in feet that object is moved in one minute [ft/min]
$\mathrm{M}=$ metabolic rate in watts [W]
$\mathrm{M}[\mathrm{W}]=104+0.095 \mathrm{~W}_{\mathrm{ex}}=104+0.095 \mathrm{~F}_{\mathrm{ex}} \times \mathrm{D}_{\mathrm{ex}}$

## Estimation of Maximum Aerobic Capacity (MAC)

Adapted from Kodak

## Distributions of Maximum Aerobic Capacity

Men
$\mathrm{MAC}=38 \pm 7[\mathrm{~mL} / \mathrm{kg} . \mathrm{min}]$
MAC $=1100 \pm 200[\mathrm{~W}]$ based on average weight of 83 kg
Women
$\mathrm{MAC}=31 \pm 6[\mathrm{~mL} / \mathrm{kg} . \mathrm{min}]$
$\mathrm{MAC}=720 \pm 140[\mathrm{~W}]$ based on average weight of 66 kg

Maximum Aerobic Capacity in Watts

|  | Percentile |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Population | $5^{\text {th }}$ | $25^{\text {th }}$ | $50^{\text {th }}$ | $75^{\text {th }}$ | $95^{\text {th }}$ |
| Men | 770 | 965 | 1100 | 1235 | 1430 |
| Women | 490 | 625 | 720 | 810 | 945 |
| $50 / 50$ Mix | 535 | 710 | 875 | 1100 | 1360 |

Note: If the metabolic rate is predominately driven by upper body efforts and no involvement of the legs, then you may wish to consider reducing the MAC by $30 \%$. That is, the $\mathrm{MAC}_{\text {upper }}=0.7 \mathrm{MAC}$.

## Design Goal: Maximum Aerobic Capacities for Least Fit Workers

| Source | $\mathrm{mL} / \mathrm{kg} \cdot \mathrm{min}$ | $\mathrm{kcal} / \mathrm{h}$ | Watts |
| :--- | :---: | :---: | :---: |
| Kodak | 27 | 570 | 660 |
| NIOSH Whole Body | 27 | 560 | 660 |
| NIOSH Upper Body | 19 | 400 | 460 |

Assumes an average body weight of 70 kg .
Experience indicates that using a value greater than the $5^{\text {th }} \%$ ile is protective of most workers.

## Endurance Time [min] versus

## Percent Maximum Aerobic Capacity [\%MAC]

From Bernard and Kenney
\%MAC $=($ Metabolic Rate $/$ Maximum Aerobic Capacity $) \times 100 \%$
$\% \mathrm{MAC}=100 \% \mathrm{M} / \mathrm{MAC}$
For a $\% \mathrm{MAC}$, either for an individual or for a design limit, the endurance (maximum work) time is read either from the left axis and the left curve for $\%$ MAC between 40 and $65 \%$ or from the right axis and right curve for $\%$ MAC from $65 \%$ to $100 \%$.

For a required work time, the greatest $\% \mathrm{MAC}$ is read by starting from the left axis for time between 25 and 250 min to the left curve or from the right axis to the right curve for times less than 25 min .
$\mathrm{t}_{\text {end }}[\mathrm{min}]=10^{\wedge}(4-4 \% \mathrm{MAC} / 100 \%)$
(This endurance time represents a minimum value for a population at a given \%MAC.)

## Recovery Time [min] versus Work Time [min] and Percent Maximum Aerobic Capacity [\%MAC]

For a specific work time read up to the $\%$ MAC curve, either for an individual or for a design capacity, and read the minimum required recovery time [min].

This family of curves can also be used (1) to specify the maximum work time for an allowed recovery time at a specific $\%$ MAC or (2) to specify a maximum $\% \mathrm{MAC}$ for a given work time and recovery time. Generally, the curves stop near the endurance time for a specific $\%$ MAC curve.

These curves assume an 8 -hour work day and use the accepted limit of $33 \%$ maximum aerobic capacity for an 8 -hour day.
$\mathrm{t}_{\text {rec }}[\mathrm{min}]=\mathrm{t}_{\text {work }}(\% \mathrm{MAC} / 100 \%-0.33) / 0.23$
